ABSTRACT
In traditional body-art, designs are adjusted to the body as they are applied, enabling creative improvisation and exploration. Conventional design and fabrication methods of epidermal interfaces, however, separate these steps. With BodyStylus we present the first computer-assisted approach for on-body design and fabrication of epidermal interfaces. Inspired by traditional techniques, we propose a hand-held tool that augments freehand inking with digital support: projected in-situ guidance assists creating valid on-body circuits and aesthetic ornaments that align with the human bodyscape, while pro-active switching between inking and non-inking creates error preventing constraints. We contribute BodyStylus’s design rationale and interaction concept along with an interactive prototype that uses self-sintering conductive ink. Results of two focus group explorations showed that guidance was more appreciated by artists, while constraints appeared more useful to engineers, and that working on the body inspired critical reflection on the relationship between bodyscape, interaction, and designs.

1 INTRODUCTION
The skin offers appealing properties as an input surface: it is large and always available, soft and deformable for expressive interaction beyond touch [98], while its tactile perception eases eyes-free interaction [20]. Prior research in and beyond HCI has explored a multiplicity of materials, fabrication techniques, and design approaches for exploring these properties in epidermal interfaces. They typically follow a three-step workflow: (1) designing the interface on a computer, e.g., using graphic design software [32, 46] or custom software tools [48, 56]; (2) fabricating the design, e.g., using screen printing [46], stencil or laser cutters [32, 48, 97], inkjet printers [35] or lamination techniques [48]; and eventually (3) applying the epidermal interface to the body, e.g., through water-transfer [46].
Recent work by Choi et al. [9] succeeds in merging steps 2 and 3 into one unified on-body fabrication step using an attachable printing device and conductive ink. Nevertheless, all of these approaches require an initial digital design step, separated from the body. In contrast, we wish to support the hands-on adaption of designs to the human body as is common in established body-based practices including tattooing, makeup, and henna.

Such direct on-body design enables fitting epidermal devices to the human bodyscape, e.g., making fine adjustments according to detailed shape and movement of the body, and supports in-situ creative exploration and expression. Pioneering work on computational on-body design and fabrication has so far been restricted to the fabrication of passive designs without interactive functionality [16, 17]. The addition of functional elements, however, is particularly challenging due to the complex interplay between circuitry, bodyscape, and aesthetics. Techniques from traditional on-body arts and crafts underpin the importance of a tight link between the design and the individual body size and shape. With this in mind, we aim to explore combined design and fabrication of functional epidermal devices directly on the body.

We present BodyStylus, the first computer-assisted approach for freehand on-body design and fabrication of epidermal devices. BodyStylus consists of a general concept, inspired by traditional body-art, a system including a handheld marker (Figure 1a), and a set of design techniques for creating epidermal interfaces. The handheld marker enables on-the-fly design, customization, and fabrication of epidermal interfaces directly on the user’s body. The system supports the user in implementing functional devices respecting electronic constraints, aesthetics and body features: projected in-situ guidance facilitates functional and aesthetic results, while automatic switching between inking and non-inking modes prevents errors in circuit logic. We demonstrate the technical feasibility of BodyStylus with a proof-of-concept implementation using a custom-designed dispensing pen and self-sintering conductive ink to instantly create functional traces on epidermal devices.

The design techniques offer the user a rapid, direct, and hands-on way of creating visually aesthetic epidermal devices on the body. Based on varying levels of guidance and constraints, we offer techniques for inking functional conductive traces, creating aesthetic shapes and patterns, adding electronic components, and creating custom free-form components.

We show how these techniques can be used in concert to design and fabricate functional epidermal devices, alone or collaboratively, for various body locations. We demonstrate that BodyStylus reflects aesthetic and artisanal paradigms of traditional on-body arts and crafts, while also offering a means of facilitation and guidance orthogonal to traditional crafts.

In two focus groups, BodyStylus was practically explored with engineers and makeup artists. The findings uncover commonalities and differing perspectives as well as suggestions on how the practitioners would wish to incorporate it into their own workflow. The aspiring make-up artists were able to implement epidermal controls for special-effect LEDs within less than two hours after having learned about the concept of epidermal devices. Our observations further show that working on the body inspired critical reflection on the relationship between bodyscape, interaction, and design.

2 RELATED WORK

Our contribution builds on prior work on epidermal devices, interactive fabrication, sketch-based interfaces, and flexible electronics.

2.1 Epidermal Devices

Building on pioneering work on epidermal electronics [37], the HCI community has proposed using on-skin devices for interactive purposes [97]. Various forms of input and output on the epidermis have been investigated, including multi-touch input [56], visual feedback [32, 46, 95, 99], haptic output [22, 23, 52, 102, 105], stiffness change [31], and customized physiological sensing [55]. Fully wireless solutions can be realized [48].

The body has a complex geometry with many recognizable landmarks [88]. Such complex features of the body can be used to provide additional haptic guidance [99] and serve as mnemonic aids in interaction [3]. The importance of aesthetics for the social acceptability of body-worn interfaces has been emphasized early on. Cosmetics and traditional body decoration served as important sources of inspiration. For instance, Vega et al. [92] and Kao et al. [33] demonstrate how something as personal and customizable as makeup can be turned into an interface. Other work has presented approaches for the aesthetic design of on-skin electronics [46, 97] and functional tattoos [93]. In these works, even though various levels of customization exist, the design process is separated from the body and happens prior to the fabrication.

More recent work has started to investigate the social acceptability of on-skin devices [106, 107], a theme tightly coupled with body art and tattooing [75]. Along these lines, input (or inking) on someone else’s body [12, 89] as well as the impact of interactive body markings on the wearer’s social image [40, 106, 107] are emerging areas of study. BodyStylus does not explicitly seek to investigate social issues around interactive body markings, but could serve as a tool to further investigate on-body co-creation and facilitate the design of socially acceptable on-body interfaces, by making the chosen body location (c.f., Harrison et al. [24]) more directly apparent during the creation process.

2.2 Interactive and Handheld Fabrication

Interactive fabrication allows for real-time manipulation of a fabrication device [51, 101]. Our approach is inspired by concurrent interactive fabrication, where design and fabrication occur at the same time, often controlled with a handheld device. For instance, the influential FreeD device uses a handheld milling tool to sculpt and carve 3D models [110]. Further research leverages on handheld tools for various fabrication activities, such as cutting 2D surfaces [77], making 3D models [63, 64, 78, 90, 108], spray painting [85], or creating e-textiles [39].

A comparably small number of approaches focused on interactive fabrication around the body. Tactum [16] uses on-skin gestures to design 3D models directly on the body. ExoSkin [17], an important source of inspiration of our work, extends this approach to direct on-body fabrication using a custom handheld extruder. Both approaches are limited to fabricating passive geometries. In contrast, Zhu et al. [109] and Choi et al. [9] presented devices for printing conductors directly on the skin. However, they use a conventional CAD design-then-fabricate approach. We contribute to
this line of work by presenting the first computer-assisted approach for direct on-body design and fabrication of epidermal electronics.

### 2.3 Sketch-based Interfaces

Sketching is a highly expressive medium [29]. Combining it with interactive user-interface tools gives the designer more flexibility and freedom to create design prototypes [43, 44]. A long history of research on sketching interfaces informed our use of visual real-time guides [103], pen-based position tracking [36, 38, 45, 104], and projected output [87]. Inspired by prior works and traditional body-art practices, we use a sketch-based interface to assist the designer in drawing the epidermal device on-the-fly on the body.

### 2.4 Prototyping of Flexible Electronics

Conventional approaches for creating flexible electronics commonly involve techniques of printing [6, 34, 35, 58], patterning [19, 81], or textile processing [21, 66]. To facilitate more rapid hands-on prototyping, researchers proposed using a conductive stylos or conductive paint [5, 49, 53, 67] or copper tape [81] directly on real-world objects. Prior research prominently highlighted the relevance of aesthetics in designing circuits [5, 71, 72]. Digitally designed tools for flexible electronics [26, 57, 58, 73] mainly focused on supporting novices with parametric electronic components to create electronic devices. We took inspiration from the direct hands-on fabrication of circuits using a stylus and digitally support users to create parametric components, but in contrast to this prior work, we directly design them on the body.

### 3 DESIGN CONTEXT

In this section, we take a close look at off-body and on-body work practices of established arts and crafts, and describe the design opportunities for BodyStylus that result from the unique combination of aesthetics, human bodyscape, and circuit logic.

#### 3.1 Draw on Aesthetically Rich Traditions

Body markings are a time-honored and recurrent motif in the history of civilization: ocre body-paint on ritual performers, which might be considered one of the first expressions of human art, was used as early as 147,000 years ago to augment faces and bodies [96]. Permanent tattooing [15] and henna markings [60] have a long and complex history. Contemporary body markings include permanent tattoos of various styles [69], various forms of the non-permanent face and body paint, e.g., cosmetics, stage or carnival make-up, as well as semi-permanent drawn-on skin embellishments [27] from plant-based dyes, e.g., henna or jagua.

What many of these traditions share is that they work with handheld tools directly on the body and that the tools they use shape the aesthetics of the body marking and vice versa. For instance, depending on the desired aesthetic, a tattoo might be created using a tattoo machine vs. using so-called hand poking. In henna art, aesthetics evolved around what the available tools and materials afforded. Varying pressure applied to the henna applicator affects the geometry of the resulting shape, e.g., by creating a droplet. This tight coupling of the hands-on tool, ink, and skin contrasts with existing practices around on-skin devices, such as electronic tattoos, which are mostly designed and fabricated off-skin and only then applied.

**BodyStylus** builds upon these rich traditions of elaborating a design on the body by enabling the user to *generate circuits using a pen on skin*. Thereby, the process of fabricating on-body interfaces becomes more immediate and less detached from the body than CAD-based approaches. In its aesthetic, BodyStylus strongly draws on the intricate line art of henna, which, with its crisp lines and entwined ornaments is well suited for implementing electrical circuits.

#### 3.2 Relate Bodyscape, Ornament and Function

Many traditional on-body arts and crafts incorporate the individuality of the human body into their practices: designs are adjusted to the unique size and shape of the body – often as they are applied. For instance, tattoo artists would transfer a tattoo stencil onto the desired body location, and then iteratively tune body location, size and orientation in communication with the client. If corrections are needed, they would remove and re-apply the stencil, or sketch adjustments using sterile skin scribe markers [94]. Characteristically, templates used in maternal henna are often round and symmetrical, but the mother’s belly is usually not. During application, the henna artist would then adjust the design on-the-fly by correcting for the belly’s size, e.g., by adjusting the ornament’s symmetry to fit the belly button’s position [70]. In contrast, current design and fabrication techniques for epidermal interfaces do not afford such on-body adjustments to the individual bodyscape.

In addition, a marking’s function can both follow and dictate its body location. Many types of body markings serve functions reaching beyond purely aesthetic or ornamental purposes. Traditional henna markings act as luck or fertility charms and are used in folk medicine [60]. In these applications, the marking’s location is, for instance, determined by its healing purpose: archaeological evidence hints that ancient healing tattoos (e.g., found on ‘Ötzi’) overlap with acupuncture points found in Chinese medicine [13, 41]. More recently, permanent ‘Medical Alert Tattoos’ have gained momentum, e.g., to alert first responders to chronic conditions such as diabetes [8, 42]. Contemporary henna markings may also serve to indicate marital status [80] or as a sign of having participated in elections [30], and even for advertisement [74]. In these cases, markings are placed where good visibility and immediate discoverability can be achieved.

Similarly, the on-skin placement of modern sensing technology follows body landmarks [99]: sensors might be placed where they achieve accurate measurements and avoid stigmata, haptic actuators where tactile acuity is largest, and display elements where they are highly visible. As a result, bodyscape and circuit function form a two-way relationship, where characteristics of the body motivate choice and placement of circuit elements, and vice versa. In consequence, unlike e.g., paper circuitry design, on-body design needs not only to follow “electrical, material, and visual design principles” [47], but also adhere to design principles imposed by the user’s bodyscape.

**BodyStylus** supports the designer in on-the-fly customization of designs, directly on the body, to fit the individual bodyscape they want to apply it to. This way, BodyStylus achieves compliance with
the inherent diversity of human bodyscapes and allows matching body location to interface function.

3.3 Mind Constraints from Geometry and Circuit Logic

Electrical circuits contain a layer of invisible information, i.e., their inherent logic and physical rules, for instance, polarity and continuity. In consequence, circuit construction is challenging to novices, designers, and even hobbyist makers, as it involves the risk of violating electronic design rules (e.g., miswiring, short circuits) [4, 47], erroneous component selection [4], and creating functional errors [47]. When drawing circuits on skin, these issues intensify: all traces might look the same, but their functions are not. Some are essential to keep the circuit intact, some have to be isolated from each other to avoid short circuits, while others might be purely ornamental and open to artistic freedom. Combining circuit logic and artistic design increases the complexity of the circuit, making it harder to understand and debug [54]. In addition, the resistance of the circuitry can depend on the thickness of ornamental traces and on the type of conductive ink used - a characteristic which designers might find challenging [1].

BodyStylus implements free-form drawing and allows for artistic expression, but also ensures circuit logic and aesthetic qualities, such as symmetry or harmonic repetition. To achieve this, BodyStylus continuously adapts to the user’s input by physically preventing mistakes that would compromise circuit logic (e.g., avoiding miswiring), or by dynamically responding to adaptations introduced by the user (e.g., change of scale).

3.4 Use Guides for Planning and Facilitation

There are aesthetic elements that are difficult to “get right” in free-form drawing, e.g., circular, repetitive, and evenly spaced shapes or straight lines. Many traditional on-body arts and crafts apply guides to facilitate complex shapes while finalizing and perfecting designs on the body. In tattoo art, the creation of stencils is considered an art on its own [94, 100]. While some freestyle tattoo artists despise the use of stencils as amateurish [14, 84, 94], thermal transfer stencils are today widely used to provide an outline for the tattoo artists to fill in. Similarly, off-the-shelf templates are rarely used by experienced henna artists, who instead rely on skill and muscle memory. Nevertheless, guiding tools and techniques also exist in henna art: for large henna ornaments, where spatial division is crucial, motifs are typically planned by “dotting” or outlining large elements first, and filling in details later. Guidance grids can ensure even spacing [11], and imprints from cookie cutters facilitate the free-hand application of round or symmetric shapes [79].

Stencils as guidance tools have limitations. They negatively impact the crispness of lines in make-up art and can be distorted when applied to cylindrical or convex body shapes. In addition, some guidance techniques are not directly applicable to skin. For instance, henna artists would typically practice shapes and patterning techniques on an acrylic sheet with a template underneath. When later creating henna art on skin, the artist can recall the practiced shapes or techniques from muscle memory without requiring additional guidance. This highlights how guides are useful in the learning process, specifically in skill-building activities, which has also been shown by prior work in HCI [82]. In addition, some types of guides (e.g., plastic henna stencils) confine the skin patch where ink or paste can be applied to. For instance, by creating a physical barrier. Yet, the use of more restricting or proactive guides, while known in HCI (e.g., for error prevention as in [111]), is rare in traditional crafts and underexplored in the area of on-body art.

BodyStylus enables temporary sketching of circuits, patterns or shapes, and allows using guidance marks. The users can iterate upon these virtual sketches. Once they are satisfied with their sketch, they can switch to inking mode and elaborate on the actual circuit re-using the sketch as guidance and applying constraints where needed.

4 BODYSTYLUS

BodyStylus supports designing and implementing epidermal interfaces directly on the body. BodyStylus consists of a general body-art inspired concept, a system including a handheld marker (Figure 1a), which enables on-the-fly design, and a set of design techniques. We now present the implementation of the BodyStylus system and introduce projected guidance and dynamic constraints as two core features to assist the user in creating epidermal interfaces that are functional, aesthetic, and customized for an individual’s body.

4.1 Implementation

BodyStylus, shown in Figure 2a and 2b, uses a position-aware handheld pen that can proactively switch between different modes – inking and non-inking – and that supports the fabrication of both conductive and non-conductive traces. The choice of a handheld inking device builds upon tools used in traditional body art. It allows for rich practices of designing and fabricating on and with the body, individually or collaboratively as a social activity.

Position Tracking. As a rapid means of prototyping high-resolution position tracking, we opted for using a smart pen relying on printed patterns [62]. For this purpose, the current prototype is based on a Neo SmartPen M1 [86].

Tattoo Substrate. A temporary tattoo patch insulates the electrically functional parts from the body and provides the smart-pen with a trackable pattern. The pattern is laser printed onto a patch of temporary tattoo paper [61]. The tattoo paper is covered with a layer of impasto gel [18] (~0.15 mm). The gel prevents excessive distortion of the trackable pattern by slightly evening-out the skin.

Figure 2: The handheld device includes a smart pen, multiple pen tip sizes, refillable cartridge with conductive or non-conductive ink or conductive ballpoint pen, and a servo motor. (a-b) The motor can retract the ink pen to prevent inking. Extended functionalities are accessible on the user interface menu (c).
sent to a C# host application using Bluetooth. The C# application uses OSC to pass position updates to the BodyStylus UI, implemented with JavaFX. The UI communicates with an Arduino microcontroller using the Arduino-serial-connector library to control the servo-motor which controls the inking tip.

4.2 Assistance Through Guidance and Constraints

BodyStylus considers three high-level design parameters: the aesthetics of visual patterns, the bodyscape of the user, and circuit logic. This creates a demanding design space. Users who are experts in all three areas may create a functional and aesthetic on-body circuit by free, unassisted drawing with a conductive pen. However, most users will need assistance in at least one, or multiple areas. BodyStylus combines the ease, directness, flexibility, and creative power of freely drawing on the body with various levels of assistance through two key concepts that underlie our design: guidance and constraints.

Guidance. BodyStylus guides the user with visual cues projected on the body. Guides assist the user in getting the logic of the circuit right. E.g., while the user is drawing a conductive trace, guides may suggest a routing or may highlight terminals to connect to. Similarly, aesthetic elements might be difficult to get right in the free-form drawing, e.g., repetitive or evenly spaced shapes, as well as detailed ornamental features might be difficult to draw consistently. Here, visual cues are used to guide the user in optimizing their free-hand work. Furthermore, guides help the user in choosing valid body locations for components that depend on a specific positioning on the body.

To support improvisation during the inking process, guides can be set to adapt continuously while the user is sketching (see Figure 3). Hence the user can decide at any point to follow a design suggestion or not. In the latter case, the visual guide is updated to be in line with the modified design.

The level of detail of guides can be adjusted to adapt to the user’s expertise and the desired degree of creative design freedom. For instance, visual guides can simply project outlines or directional indicators but if desired can include full details of a design, e.g., the detailed routing of a trace or the full visual pattern of an ornament.

Constraints. To prevent the user from inadvertently violating constraints relating to circuit logic, aesthetics, or body location, the pen can automatically switch between an inking mode and a non-inking mode. This enables the system to physically restrict the user’s inking actions. For instance, when the user is about to create
a short-circuit, the pen can automatically stop inking by moving the tip of the cartridge up.

To free up creativity but provide safe boundaries for flexible exploration, the system allows the user to suspend constraints with a “manual override” (c.f., Zoran et al. [111]). In this case, the user repeats the desired action a second time to override the constraint.

Despite the pen only offering two distinct interactive modes (inking and non-inking), we define the constraint space as a continuum that allows more or less tolerance. At the strictest, it prevents any inking that was not planned out by the initial design (e.g., deviating from an original aesthetic). At the lowest level, it does not restrict the user’s actions at all. Between the two extremes, it allows deviations within a certain margin, as defined by the user (see Figure 4).

Guidance and constraints can be flexibly combined throughout the design and fabrication process. This creates a two-dimensional space for interacting with BodyStylus, visualized in Figure 5. Depending on the current design task and her expertise, the user may benefit from more or less guidance and more or less constraints, for working on circuit logic, aesthetics, and bodyscape.

5 DESIGN AND FABRICATION TECHNIQUES

We now present a set of interaction techniques for on-body design and fabrication with BodyStylus and describe how these are shaped by constraints and guidance (see also Figure 5).

5.1 Temporary Sketching and Free, Permanent Inking

Before any part of the design becomes permanent, one can use the pen to draw virtual lines in the non-inking mode. These might be used to sketch an outline of the design or to experiment with how lines might complement the shapes of the body. As these virtual lines are not physically inked but merely indicated using visual feedback, users can move, scale, delete, and redraw as they wish. If one is certain of the pattern one wishes to place on the body, BodyStylus supports drawing of conductive and non-conductive traces by switching to the inking mode.

Figure 4: Constraints can be imposed at different levels. In this example, a strict constraint forces the user to closely follow the projected shape primitive (yellow circle, a). A soft constraint allows the user to deviate within a certain margin, for creative adjustments (b). Without constraints imposed, the user can draw freely, while still benefiting from high-level visual guidance (c).

5.2 Inking Visual Designs

In inking mode, BodyStylus offers primitives as visual guides for artists to develop their designs, patterning tools to support artists in creating repeating patterns and motifs for adding specific predefined elements to the design.

Shape primitives such as line, circle, and spiral provide guidance to orient or outline the design. For instance, the user can select the circle tool, then specify its center and radius with a stroke to use it as a guide to draw a flower.

Repeating patterns are an important characteristic of henna art, which we draw on for aesthetic inspiration. We provide visual guidance for creating multi-axial symmetries, repetitions of patterns, and fractal patterns. As an example, to draw a complex pattern with radial symmetry, the user selects the radial symmetry tool and locates the center point on the canvas (Figure 6a). The user selects the number of radial axes and (Figure 6b) sketches the desired design in one of the sectors (Figure 6c). The pattern is then projected in all other sectors for the user to trace (Figure 6d).

Finally, the user can select to transfer motifs to the body. The user has the option to select one of the available patterns (e.g., horseshoe or curlicue) or upload an SVG line graphic. This shape is then projected on the body at a location specified by the user. Here the system expects the user to trace the projected lines. If the user deviates from the projected line, the system scales and rotates the shape to allow the user to dynamically adjust the shape through drawing (Figure 3). Constraints can be used to limit the amount the user can deviate from the predefined shape.
Figure 6: Radial symmetry tool enabling rapid designs of repeating patterns, building on practices from henna art. The user positions the center of the symmetry axes (a), these axes appear as guides (b), the user draws the geometrical pattern in one sector (c), the pattern is replicated in the other sectors (d).

Figure 7: Constraints prevent invalid connections of conductive traces. The user draws a conductive trace to connect two terminals (a). As she is about to connect to another conductive trace and create a short-circuit, the pen retracts to non-inking mode (b). Moving the pen away from the original trace switches the pen back to inking mode (c).

Here, guidance is consecutively increased. *Primitives* are merely used as helper lines and remain unaffected by the user once placed. *Tools* for *repeating patterns* allow the user to create detailed templates – the system assumes that the user will trace this, but it is not enforced. Finally, *motifs* assume the user will always trace them, even dynamically updating to adjust to the user. In the dimension-space on Figure 5, we move from left *primitives* gradually further right *repeating patterns* and further up for *motifs*.

### 5.3 Inking Functional Conductive Traces

BodyStylus is designed to support inking electrically functional designs. In doing so, the user should be supported to create valid circuits while at the same time being free to creatively adjust the design to their desired visual aesthetics. For instance, instead of drawing the most efficient connection between two components, users might deliberately deviate to create a more aesthetically pleasing result, or augment a trace with artistic elements, e.g., curlicues.

Again, the interaction methods are based around an interplay of *guidance*, which shows the users which traces or pads can connect, and *constraints*, which physically prevent the user from creating invalid connections (short circuits, wrong polarity – see also Figure 7). To achieve this, the system requires a model of the underlying electrical circuit; BodyStylus records the precise location of the pen on the body while inking and saves this data as a vector graphic. In addition, the system tracks the position and polarity of the embedded components and distinguishes between functional and artistic traces.

For working with electrically functional traces, BodyStylus supports four levels of guidance (Figure 8). To work completely freely, users might choose *no guidance* (Figure 8a). To add some visual support *minimal guidance* can be chosen to highlight which other pads the current trace can connect to (Figure 8b). If using *partial guidance*, a direct path to a suggested destination pad is highlighted (Figure 8c, dashed line). Finally, *complete guidance* shows a path the user needs to trace to complete the circuit. This path might include basic routing (using the A* algorithm [25]) and can include visual styles for aesthetic effects (Figure 8d). The desired style is manually chosen from a library of patterns. The above guidance methods were described from left to right of the dimension space in Figure 5. They can be crossed with continuously varying levels of constraints, which change the margin of how close one may come to making an error before the pen retracts, moving up or down in Figure 5.

### 5.4 Placing Electronic Components

To assist users in adding standard electronic components to the epidermal circuits, BodyStylus contains a library of frequently used components. Our current implementation comprises resistors, capacitors, diodes, LEDs, inductors, and breakouts for connecting cables. Additional components can be implemented: for each component, the library stores the package type and function of pins.

Using this information, BodyStylus visually guides the user in placing the component. After selecting a component from the library, the user defines the location of the first pad (Figure 9a) and drags the pen to locate the last pad. The system guides the user by projecting the distance and angle between pads (Figure 9b).
Figure 10: Parametric components. The user places a bend sensor design on the wrist (a) and enhances its visual aesthetic with a curlicue pattern. She drags the center, which modifies the pattern on-the-fly (b). When moving the sensor to a body location the user cannot bend, the body constraint is highlighted in red (c).

After releasing the pen, the system displays the component’s footprints (Figure 9c). To make the design permanent, the user starts inking the pads. The system constrains painting outside the footprints’ borders and connection between terminals by retracting the pen (Figure 9c). Finally, the user places the components (e.g., LED) and connects the wires to the terminals using conductive paste as glue [10] (Figure 9d). Due to the requirements for strict constraints, these interactions are at the top of the dimension space in Figure 5.

5.5 Free-Form Components

Some commonly used types of electronic components can be hand-drawn in free-form using conductive ink, e.g., capacitive touch buttons, sliders, resistive bend sensors, strain gauges, or coils. These provide two opportunities: (a) the user can adjust their function to meet the specific demand of the system (number of windings in coil, length of bend sensor, number of pads on a slider, etc.), and (b) the user can adapt their aesthetics to match the overall design.

To provide support for these activities, BodyStylus offers a library of parametric designs for free-form components (resistive bend sensors, capacitive sliders, and coils; additional components can be added, similarly to electrical components). To create a free-form component, the user selects a parametric design and places it on the body (Figure 10a). The design can be moved, scaled, and adjusted in visual style (Figure 10b). If body placement constraints are violated (e.g., placing a bend sensor at a location that cannot bend), the component is highlighted in red color (Figure 10c). When satisfied, the user can ink the traces with conductive ink. Of note, the user is free to creatively deviate from the design and to add ornaments that match the aesthetics of the overall design. Figure 11 shows various examples of how the user can flexibly adapt the basic parametric design to create different aesthetics. Of course, a specific aesthetic style can be encapsulated as part of a parametric design, too. For instance, the slider component allows the user to choose from several visual styles for the conductive line.

Creating parametric components borrows from previously introduced interaction methods: terminals are implemented as electrical components, connections within the free-from component are implemented as described for electrical traces, and specific shape features are implemented as described for aesthetic patterns. Of course one can combine these with inked visual designs (see also Figure 9), and temporary sketching can be used for quickly testing ideas before permanently implementing them.

6 EVALUATION

To validate the practical feasibility and to investigate opportunities and limitations of the BodyStylus concept, workflow, and example implementation, we present (a) examples of implemented designs alongside lessons learned, including a detailed walkthrough of how one of these designs was created and (b) feedback from a focus group exploration with three stage make-up artist trainees and a focus group exploration with three engineers.

6.1 Application Cases Realized with BodyStylus

To demonstrate the end-to-end feasibility of epidermal interfaces, we present four example application cases we have designed and fabricated with BodyStylus: an interactive hand adornment, a wirelessly powered epidermal interface, a wristband control, and a decorative anklet. The functional prototypes are shown in Figure 12.

Figure 11: Custom free-form components can be created by selecting a parametric design (leftmost column) and then customizing it in size and style.

Figure 12: Interactive Application Cases. Interactive hand decoration that responds to body movement (a); wirelessly powered interface (b); wristband slider control (c); decorative anklet (d).
6.1.1 Interactive Hand Decoration. Inspired by interactive makeup such as Kinisi [91] and traditional bridal henna [60], we decided to create an interactive adornment that reacts to hand movement with light (Figure 12a). To describe the design and fabrication process, we present a step-by-step walk-through of this application case before presenting the three other application cases more briefly.

An important part of practicing body-arts is the preparation of the body, for example, a make-up artist applies a coat of primer to create a blank slate. Similarly, the empty substrate provides a blank slate for drawing on, and its placement already foreshadows its potential use. In this case, we placed the empty tattoo on the hand and wrist to support the implementation of a bend-sensor and hand adornments.

Henna artists usually start their work by “placing dots” as guidance for subsequent patterns. We decided to start with the bend sensor and, similarly, initially placed control points where other parts of the circuit will later connect to. Once satisfied with the placement, the terminals were made permanent by inking them and choosing a visual style for the sensor (Figures 13a and 13b).

Artists consider the body’s movements as an important reason for working on the body, to see the movement of the person and to see the response of the materials. Similarly, designing the bend sensor directly on the body allowed for exploring where exactly the wrist moves and deciding how the electrical traces cover this movement (Figure 13c). The position and size of the sensor relative to where movement occurs both influence the function of the design. At the same time, the pattern selected for the sensor shapes the design’s aesthetics. For now, we did not ink the traces so we could return to tweak and fine-tune them later.

Next we started sketching a flower design. As its center will be an LED, we first defined its footprint (Figure 13d). Then, we started sketching its adornments. Here the use of the radial symmetry tool was again reminiscent of traditional henna practice, e.g. drawing a crosshair as guidance. Similarly, we defined a 6-segment crosshair (Figure 13e), which we used to create a repeating pattern (Figure 13f). We then proceeded to immediately ink it using non-conductive ink (Figure 13g). Satisfied with our arrangement of the flower and sensor (Figure 13h), we also inked the sensor using gold ink as well as the connectors to the LED with conductive silver ink, using free inking without guidance (Figure 13i). In case of an error, BodyStylus would prevent us from creating a short-circuit or from inadvertently connecting to the bend sensor.

In traditional henna practice, once bridal henna has dyed the skin and the paste is removed, it is not uncommon to add gemstones or other adornments, which are quite literally glued to the skin. Much in the same way, we finalized our design by placing the LED (Figure 13j) as well as connecting our prepared traces to an Arduino micro-controller. The finished piece can be seen in Figure 13k. When the wrist is flexed, the resistance in the bend sensor increases and the LED is turned on (Figure 13l).

6.1.2 Wirelessly Powered Epidermal Interface: Inspired by [32], we set out to design and fabricate an epidermal interface for use on one’s upper arm that is wirelessly powered (Figure 12b). It features an LED embedded inside an aesthetic line-art design. When powered using an off-the-shelf wireless charging coil [50] held in close distance to the interface, the LED lights up. We selected the Coil free-form component and used visual guidance for creating a spiral that acts as a receiver coil for inductive power transmission. We used conductive yarn with a non-conductive coating to close the coil. As the conductivity of the conductive gold ink is not high enough for creating an induction coil, we realized the spiral with silver ink. For a visual style similar to henna dye, we then repeated the trace with gold ink. To make the design aesthetically pleasant, we experimented with several ornamental shapes and decided to surround the spiral with a paisley design, a key element of henna art, using free inking.

While creating the design, we realized that the use of impasto gel underneath the temporary tattoo substrate allows the substrate to be removed and re-applied multiple times. This creates opportunities for combining the benefits of on-body design with working off-body for tasks such as finishing complex patterns or debugging. The design has been done collaboratively on the body and fitted to the size and dimension of the user’s arm, and then finalized on a table before it was transferred again to the body.

6.1.3 Wristband Slider Control: In our third application case, we aimed to investigate capacitive sensing. We have realized a wristband that comprises a capacitive slider with three segments and an RGB LED (Figure 12c). We selected the slider free-form component and used visual guidance to design and fit the size and number of segments to the wrist. The full constraint prevented us to connect the segments to each other inadvertently. Using projected guidance, we could design several sliders with different sizes, shapes, and number of segments at different angles to find the most suitable design without investing time to fabricate them. The device was created by a single user on her own body, and then connected and controlled with an Arduino microcontroller. In our proof-of-concept, the capacitive slider is used to adjust the color of the LED;
We conducted two hands-on explorations to collect feedback of working understanding of what epidermal devices are. After providing hesitation before inking each other, however, the engineers took came naturally to the make-up artists, who do so in their day-to-day practice. Working on other people’s bodies for bodily exploration.

6.2 Focus Group Explorations

We conducted two hands-on explorations to collect feedback of BodyStylus in use, following an approach that has proven valuable to connect with craft experts [7].

6.2.1 Method. The first exploration was conducted with three engineers familiar with designing circuitry, having backgrounds in embedded systems (E1, female, 24), robotics (E2, male, 28), and physiological sensing (E3, male, 30). The second group consisted of three professional stage make-up artists, all female, aged 26 (A1), 22 (A2), and 19 (A3), and experienced with a wide repertoire of on-body techniques, including the use of different mediums, pigments, and tools.

Before the exploration, we ensured that all participants had a working understanding of what epidermal devices are. After providing informed consent, both groups were asked to perform a series of tasks designed to elicit discussion and feedback. The sequence of tasks was arranged from simple to more complex, to allow participants to become familiar with BodyStylus. They were asked to (1) draw two intersecting lines on a mannequin, using the projection for guidance, and automatic retraction for constraints; (2) create a freehand pattern including one interface element (e.g., a button) on one of their colleagues; and (3) collaboratively design and implement a functional prototype. For the engineers, this was a generic controller, while the make-up artists were tasked to build a device for controlling RGB LEDs as used in a design they were working on at their theatre. We paused after each task, inviting critique and introspection. Sessions were audio-recorded, and photos of key situations were taken. Claims about the system, applications, or usage were extracted into individual files, reducing the 4 hours of recording to 33 minutes of tagged quotes. These quotes were thematically grouped as reported below.

6.2.2 Results & Discussion. Both groups were able to complete all tasks and provided valuable feedback. Most critically, after less than two hours of exploration, they were able to implement their own, functional, epidermal UI without intervention from our side. We now summarize central findings by theme.

BodyStylus for Bodily Exploration. Working on other people came naturally to the make-up artists, who do so in their day-to-day practice, while the engineers tended to show short moments of hesitation before inking each other. However, the engineers took advantage of working on the body rather than in CAD software, for example, for quickly testing the positioning of UI elements on moving body parts (Figure 14b).

For task two we placed tattoo substrate on the knuckles to see how participants might integrate these complex shapes into their designs. After asking participants to create input elements, we observed different ways in which designs reacted to body features: E1 lined up her interface elements with the knuckles, while E2 superimposed a button on a knuckle. E3 chose a different approach: He drew a strain gauge over the knuckles. Make-up artists engaged with the body differently for their designs. Instead of physiology they focused primarily on the visibility of body parts. In the first design they created for task 2, A3 placed the button as far to the edge of the substrate as possible, with the intent of hiding the interface. Latter designs by A1 and A2 explored opportunities of using the button as an element visible to others.

Task three showed that the real-world application of the make-up artists was valuable in critically reflecting on design. While the engineers merely placed buttons on the arm (see Figure 14c), the make-up artists spent more time discussing and planning their final interface. They highlighted aspects such as benefits of uni-manual vs. bi-manual operation, discussed which surfaces were better suited for pressure and which for touch input, and planned on how to avoid unintentional activation. Working on the body led the make-up artists not only to think about the visual layout of the interface, but also reflect on how the epidermal UI will interact with the body when in use.

BodyStylus as Artistic Hand Tool. The engineers immediately praised the high ink-flow rate, which they felt made the device easy to use and promised robust circuits. Interestingly the make-up artists remarked negatively at the high ink-flow rate, and especially with the fact that the ink-flow rate could not be continuously adjusted while inking. They felt that this inhibited their ability to produce delicate patterns and dynamic stroke thickness. While all participants were able to adapt to the offset between the inking tip and tracking tip, the make-up artists repeatedly stated that it required active attention – especially on the uneven and compliant surfaces of the body. Interestingly this too was less of an issue for the engineers.

While we anticipated that participants might be apprehensive working with an actuated tool that could retract based on pre-determined rules, this was largely not the case. In addition, we did not observe any effect on the user’s drawing while the pen was retracting. E1 mentioned that she felt the pen should be designed to minimize recoil when the inking tip was retracted. A2 explained that because she understands the behavior of BodyStylus, it is just a tool, much like the various pens and brushes she uses in her everyday practice.

BodyStylus as Error Prevention. The engineers commented on the usefulness of constraints for positioning ICs and SMD components. Beyond that, E2 and E3 were especially excited that constraints provide them with the ability to draw finely detailed components such as strain-gauges. E2 felt that such constraints might be a useful proxy for physiological sensing, for example in place of EMG, while E3 stated that he would enjoy inking with constraints on other surfaces than the body: “whenever I build something with

6.1.4 Decorative Anklet: To demonstrate that BodyStylus is applicable to various body locations, we realized a decorative anklet that features a blinking LED (Figure 12d). The LED footprint was selected from the component library and then placed in the desired position on the ankle. We used full detailed guidance to project the curlicue patterns between LED and the breakout footprint. The pattern was painted with gold ink and then connected to an SMD LED using bare conductive ink. An Arduino microcontroller is used to power and control the device.
elastische materials and want to measure deformation, I’d love to use this for drawing sensors”. For the make-up artists, the use of constraints for error prevention was mostly appreciated in the context of tasks requiring precise positioning and exact stroke lengths: “oh, I want this next time I do eyes” (A3). Nevertheless, it was also noted that constraints were only applicable to the very specific context of their craft, as in make-up one usually works with smooth gradients. Participants also expressed worry that over-reliance on the system might risk losing their manual skills. Along these lines, A3 stressed the importance of being able to override constraints.

**BodyStylus as Assisting Guide.** With the simple examples created during the exploration, the engineers felt that they did not need the guidance features. They did speculate that it would be useful for someone with less knowledge of electronics. The make-up artists in fact did appreciate the guidance. For instance, A3 noted that the projected guides would blend in with make-up techniques making use of the human face’s symmetry: “there are these lines [she points from nostril to outer edge of eye-socket] “which we use, and if you could project them, I would immediately use that”. The guides blend in with their existing craft. For example, A1 mentioned that “we already sometimes draw dots to guide the design” and “having this would be so much better”. All three artists stated they would want to use guidance in their everyday practice.

**BodyStylus Integrated in Day-to-Day Practice.** Interestingly, the artists’ take on how the system should be used changed while they gained more experience with it. Initially, they envisioned making use of BodyStylus for final touches or for implementing a carefully thought-out design. Towards the end of the session, they noted that BodyStylus would be most handy as a sketching tool early on in the design process. They outlined how it could enable them to rapidly create a rough on-body draft so that they would have more time to work on the final details. The engineers questioned why the system was constrained to working on the body and highlighted that they would appreciate this approach for rapid prototyping in other contexts also.

6.2.3 Summary. Participants took advantage of working directly on the body by exploring bodyscape, using the morphology of the body, and testing UI elements in-situ. Differences in expectations and goals led to conflicting assessments of the physical pen prototype. In future iterations, dynamic ink-flow should be considered, and the inking and sensing pen-tips superimposed. Both engineers and artists appreciated constraints; however, constraints are more useful to engineers, who suggested applications for constraints beyond those we anticipated. Artists worry that overrelying on constraints might prevent maintaining and developing manual skills. Inversely, guidance appeared more suitable to the artists, who this time were the ones to suggest new applications. Finally, BodyStylus not only supported complete novices in the design and fabrication of a working prototype, but also facilitated thinking about interaction and design.

7 DISCUSSION

**Occlusion and Calibration.** Our implementation of in-situ visual feedback is currently restricted to a projector, which can cause occlusion on the skin while the user is manipulating the pen. Accurate projection mapping on a moving and deforming body is still an active research field. We implemented a simple calibration step for mapping the projection to the skin site’s position, which however does not continuously update, hence requiring the skin site to remain immobile during the interaction. We experienced that this is acceptable when designing on limbs, as they can be placed in a comfortable resting position, but can be more challenging when designing on the torso. Note that thanks to the locally stable Anoto pattern, the position tracking remains accurate in case a skin site is moving in 3D space, which is important to maintain a correct digital model and ensure precise computer-controlled inking behavior. In future work, we plan to experiment with a pico projector built into the pen [87] and a head-mounted display for improving mobility and avoiding occlusions and to implement a more advanced projection mapping scheme as suggested in [65].

**Focus on Hand and Arm.** According to [24], the hand/arm space is the one most extensively used for on-body interfaces. Although our main focus is on these locations, evidence from the implemented example cases confirms that our approach works well on the demonstrated body parts (e.g., hand, forearm, upper arm, wrist, and ankle). It can be extended to other body parts, such as legs, thigh, and back (the latter requiring co-creation since self-inking is not possible on the back). On very challenging skin geometries, e.g., strongly convex body parts, the smart pen sometimes loses data points; interpolating the captured data allows estimating the pen position.

**Substrate.** Our current setup uses a substrate printed with dot patterns to enable the smart pen’s position tracking. The choice of the substrate is a pragmatic choice to support this particular proof-of-concept implementation with precise tracking and an insulation layer. However, future iterations based on BodyStylus might be designed to operate more directly on skin. One option is to make the substrate fully transparent, e.g., by printing the Anoto pattern using a transparent IR absorbing ink. Another option is to remove the...
substrate altogether, using a different position tracking technology, e.g., optical motion capturing, combined with an insulated spray primer. In addition, the strengths of BodyStylus include its support of skill-building activities using guidance and constraints as well as its ability to be used with self-sintering, skin-safe gold ink. As a result, artists could practice designs on themselves using guidance and constraints to commit drawn shapes to muscle memory, and then, removing the substrate and using only the pen with gold ink recall the practiced shape when designing for a wearer.

**Single-layer Substrate.** While our approach is currently restricted to single-layer, conductive bridges can be realized with electrically insulated conductive yarn.

**Modifying Traces.** Lastly, while our system supports users before and during inking, it does not allow the user to modify traces after they have been made. Future work should investigate erasing interactions [59] to edit the design after inking.

### 8 CONCLUSION

Until now, design and fabrication processes for epidermal devices were indirect and detached from the human bodyscape. With BodyStylus we presented a novel interactive approach that overcomes this limitation and allows us to design and craft epidermal devices directly on the body using a hand-held fabrication tool and self-sintering conductive ink. We present a palette of on-body design and fabrication techniques that leverage in-situ projected guidance and physical constraints to facilitate the creation of functional and aesthetic epidermal devices. BodyStylus is conceptually grounded on design considerations integrating circuit logic, aesthetic principles, body shape, and functionality, and expands upon the existing traditions of body markings by facilitating skill-building activities. We exemplify these parallels and starting points using four concrete application cases, where we further demonstrate how BodyStylus succeeds in creating functional epidermal devices. Our results show that our approach was positively received by stage make-up artists and constraints to commit drawn shapes to muscle memory, and then, removing the substrate and using only the pen with gold ink recall the practiced shape when designing for a wearer.

### 9 ACKNOWLEDGMENTS

This project received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation program (grant agreement No 714797, STG Interactive Skin). We thank Martin Weigel and Anusha Withana for their valuable feedback, Muhammad Hamid for his help with video editing and Robert Strahl for his support in gold ink sample preparation.
